

ABSTRACT

A liquid delivery device comprises a flow channel for flowing a liquid, at least two pressure-generating means for generating pressures provided in
5 the flow channel, and a variable member placed between the pressure-generating means and capable of transforming between a first stable state and a second stable state by a generated pressure;
the device serving to select a branch of the flow
10 channel by transforming the variable member into the first stable state or the second stable state. A valve for changeover of flow channel branches comprises a variable member placed between pressure-generating means and transformable between a first
15 stable state and a second stable state by a generated pressure, the valve serving to select a branch of flow channel branches by the variable member.
